

## 1. Difference between HTML Webpage & React Webpage

Aspect	HTML Webpage	React Webpage
<b>Structure</b>	Built using static HTML, CSS, JS files.	Built using components (JSX + JS) that render HTML dynamically.
<b>Rendering</b>	Browser loads and renders full HTML each time.	Uses <b>Virtual DOM</b> — only updates parts that change.
<b>Reusability</b>	HTML elements are static; no modular reusability.	React components are <b>reusable and modular</b> .
<b>Interactivity</b>	Needs JavaScript manually for dynamic actions.	React handles interactivity with <b>state &amp; props</b> .
<b>Performance</b>	Slower when reloading pages.	Faster updates — <b>Single Page Application (SPA)</b> .
<b>Data Handling</b>	No built-in data management.	Handles dynamic data easily using <b>state management</b> .

- HTML → Static & simple.
- React → Dynamic, component-based, SPA framework.

## 2. Difference between Angular & React

Feature	Angular	React
<b>Type</b>	Full-fledged <b>Framework</b>	<b>Library</b> for UI
<b>Language</b>	Uses <b>TypeScript</b> by default	Uses <b>JavaScript/JSX</b> (optional TypeScript support)
<b>Learning Curve</b>	Steeper — has many built-in features	Easier — focuses mainly on UI
<b>Data Binding</b>	<b>Two-way binding</b>	<b>One-way binding</b>
<b>DOM Handling</b>	Real DOM	Virtual DOM
<b>Architecture</b>	MVC (Model-View-Controller)	Component-based
<b>Size</b>	Larger bundle size	Lightweight
<b>Developed By</b>	Google	Meta (Facebook)

- Angular = Complete ecosystem (routing, forms, services).
- React = UI library; flexible with third-party tools.

## 3. What is TypeScript?

TypeScript is a **superset of JavaScript** that adds **static typing**.

### Example:

```
let name: string = "Mani";
let age: number = 25;
```

If you write `age = "twenty"`, TypeScript will throw an **error**.

### Benefits:

- Type safety (detects errors early)
- Better autocompletion & IntelliSense
- Easier debugging
- Used in frameworks like **Angular** and **React (TSX)**

## 4. Key Concepts

Term	Meaning & Example
<b>Variable</b>	Container for storing data. <code>let name = "Lunar";</code>
<b>Declaration</b>	When you declare variable: <code>let x;</code>
<b>Initialization</b>	Assign value: <code>x = 10;</code>
<b>Lexical Scope</b>	Variable access depends on where it's <b>declared in code structure</b> , not where it's called.
<b>Block Scope</b>	Variable available only inside <code>{}</code> . <code>let</code> and <code>const</code> follow block scope.
<b>Function Scope</b>	Variables declared inside function accessible only within that function. ( <code>var</code> uses function scope).
<b>Hoisting</b>	JS moves <b>declarations</b> (not initializations) to top of scope. Example: You can use a <code>var</code> before declaring it.
<b>Closure</b>	A function that <b>remembers variables</b> from its outer scope even after that scope is gone. Example:

```
function outer() {
  let count = 0;

  return function inner() {
    count++;
    console.log(count);
  };
}

const counter = outer();

counter(); // 1
counter(); // 2
```

## 5. Why Node.js is used in Web Development?

Node.js allows **JavaScript to run on the server-side**, not just in browsers.

**Reasons it's used:**

- Handles **backend logic**, APIs, and databases.
- Enables **full-stack JavaScript** (React frontend + Node backend).
- Fast — built on **V8 engine** (Google Chrome's JS engine).
- Supports **real-time apps** (like chat, live updates).

✓ In short:

**Node = Backend environment for JavaScript.**

## 6. Which came first — Node, Angular, or React?

Technology	Released Year	Created By
<b>Node.js</b>	<b>2009</b>	Ryan Dahl
<b>AngularJS</b>	<b>2010</b>	Google
<b>React</b>	<b>2013</b>	Meta (Facebook)

Order:

Node.js → Angular → React
